

ABSTRACT

A method, system and apparatus for providing a web application generator to generate the basis for a complete web application source code. Based on graphical user interface input files provided by graphic designers, the web application generator generates application framework code, an event handler skeleton and business logic foundation code. Web developers then prepare additional source code using an object-oriented programming language based on the event handler skeleton and business logic foundation code to create web application business logic objects and event handler methods. Ultimately the graphical user interface input files prepared by the graphic designers and web application source code prepared by the web developers are dynamically bound at runtime.
